

Early Journal Content on JSTOR, Free to Anyone in the World

This article is one of nearly 500,000 scholarly works digitized and made freely available to everyone in the world by JSTOR.

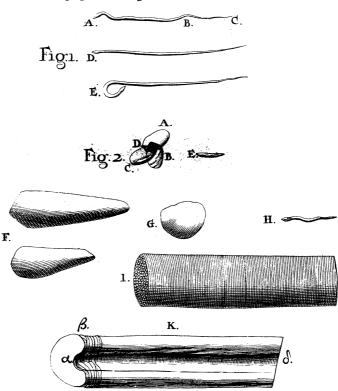

Known as the Early Journal Content, this set of works include research articles, news, letters, and other writings published in more than 200 of the oldest leading academic journals. The works date from the mid-seventeenth to the early twentieth centuries.

We encourage people to read and share the Early Journal Content openly and to tell others that this resource exists. People may post this content online or redistribute in any way for non-commercial purposes.

JSTOR is a digital library of academic journals, books, and primary source objects. JSTOR helps people discover, use, and build upon a wide range of content through a powerful research and teaching platform, and preserves this content for future generations. JSTOR is part of ITHAKA, a not-for-profit organization that also includes Ithaka S+R and Portico. For more information about JSTOR, please contact support@jstor.org.

Philosoph. Transact. Number, 152.

An Abstract of a Letter from Mr. Anthony Lecuwen-hoeck of Delft about Generation by an Animalcule of the Male seed. Animals in the seed of a Frog. Some other Observables in the parts of a Frog. Digestion, and the motion of the blood in a Feavor.

Aving been sollicitous to examine the generation of Frogs, upon the account of their young ones being like a Worm, with a round thick body and a short tayle: I was surprized to find that the Male was not joyned to the Female in Copulation, but that he only sate upon her; and had no Membrum Masculum: that at the same time when the Famale cast her Eggs or Spawn, the Male also dropt his Seed; which is to be spread under the Eggs: in like manner as the Seed of Fishes that want the Membrum Masculum is cast under the Eggs of the Female, that the Animalia in semine may conveniently impregnate the eggs. For I hold it necessary that some one of the Animals in semine should get into a certain * point of the yoak of the egg (which point is only fit to receive it, and give it the first Nourishment, till such time as the Egg comes to be fat on) But if no one Animal should find this point, then the Egg is unfruitful: and this may be a reason why there are so many thousand more Animals in semine Masculo, then Eggs in the female.

In feveral of my Observations I had not found the Animals taken out of the Testicles and Vasa Deferentia of Froggs to be alive. But on the first of April when Froggs were ready to spawn, I took some of the Males sitting upon the Females, and squeezed their hinder parts that I might get the seed out of the Vasa deferentia but the Ani-

^{*} By this point or speck be means the Cicatricula.

malcules I then found, moved but little, because the matter they were in was full of salt particles, which made me

judg it to be Urine.

I then cut open the Testicles and there I found an innumerable company of Animalcules swiming among a fort of ill shapen particles, these continued alive till the next day, tho there were but a small quantity of liquor to contain them.

I judge the Bodies of the Animalcules to have been of the thickness of part of a hair of my head: If the matter they moved in had not been so thick I should have seen them much plainer, nevertheless they are represented to the best of my skill in Fig. first where ABC is an Animalcule as it lay in the Watry matter, and moved it self therein, sometimes the head appeared to be thicker then other times, and often I could fee the Body but from A to B by reason of the thinness of the Tail BC. when the Animal moved it felf strongly, tho the progress were but little, the motion towards the head was like that of a Snake. and the tayle was cast into 3 or 4 Bows. Fig. D is an Animalcule lying dead, and stretcht out at length, but in this posture I saw but few, for many that were dead lay with the fore part of their body bent in, as in Fig. E others made as, it were a half circle others had the forepart of their Body bent and moved their hinder parts: these last I took to be ready to dye.

The number of Animalcules in all the feed was so great that I judge there might be 10000 of them to one of the Females Eggs, the same computation I formerly made of the Milt of a Codfish, but it must not be thought that all the Animals in the Milt of the Codfish live together, but only such of them as are nearest the passage they are to be cast out of, and who have more moysture about them; the rest of them being more remote in the body, and being incompassed with a thicker matter, are not alive; for tho some fishes, as the Breame, and Trout, cast their Milt and Spawn in two days time, yet Codfishes are about a Moneth

in doing it; in all which time the seed is successively ripened and perfected. So also are Froggs by what I have experienced, for the first Animals I sought were dead, and though I afterwards found live ones, yet those were dead

that lay deepest in the Testicle.

Tis well known that when a Cock hath trod a Hen but once, many Eggs are made fruitful, the reason that I give for it is, that many of the Eggs in the Ovary, have each of them received an Animalcule out of the Male seed. Animalcule while the Egg is fate upon does not presently take the figure of a Chick, but grows into a disorderly Bulk, wherein the heart is first plainly to be discerned. Other Fætus's have a different way of growth, the Louse has all its parts, and is a Breeder while it is yet in the Egg; the Flea shows like globules swimming in a watry substance, it afterwards becomes a Worm, then a Nympha. The Frog is a thick Worm till it be of a confiderable bigness. Humane Fætus tho no bigger then a Green Pea, yet is furnished with all its parts. I have often endeavoured to discover the Animal coming out of the Male feed, in the egg of the Hen; but have been unsuccessful tho some of the Globules of the Egg were magnified ro the bigness of common Apples. This disappointment has put me upon the Eggs of Insects as the Flea, and Louse, which being very small, may be so much the fitter for this discovery.

A certain Physician writing of Generation sets down these words, in the Margent from the semale seed the fruit must grow however the thing came to pass. This he inlarges upon in the Text, but I think under correction that by one instance I shall bring a sufficient proof of the fruits coming from the Maleseed, and the semales only contributing to the nourishment and growth of it. Many of our Neighbours either for their pleasure or prosit, keep tame Rabbits, which are large long eard, ordinarily of a white colour, but sometimes of a Blew, Black, and Pyed; those that would make a prossit of these Rabbets by causing them to bring gray young ones, whichinthe fore part of

[350]

the year may be fold for a wild kind; get a grey Male, fuch as are ordinarily found on our fand hills, to put to their female: The Breed that comes from hence always takes the gray colour of the Male, and it has never been feen that any of the young has had any white, or other coloured hair then gray, there withal they are never so bigg us the Dam, nor have so great ears, nor are so tame, but of a wilder kind.

The first Frog which I anatomized lay on the ground in my way, and feemed fo weak through cold that tho I kicked it with my foot, it would not leap away, this proved a Female, in the gutts of it I found worms like those in Children of about the thickness of a hair of my head. The blood confitted of flat oval particles, swiming in a clear liquor: these had no colour as they lay singly, but when 2 of them lay upon one another, as here Fig. 2d. their colour was stronger. A is an Ovale of blood partly covered with B a 2d. Ovale of blood, C is a 3d. Ovale of blood covering a part of ACB as at D. and casting a deeper colour, by reason that 3 Plates lye upon one another: But there was another small Oval hard by represented by E which showed of a higher red then the three Plates together. Many of these Ovale particles were very pleasant to look upon, especially when the moysture wherein they swam (having also Globules on the surface as big as \frac{1}{6} of a blood Globule) was evaporated; for some had in the middle a faint Ovale shade, others appeared as if they were made of feveral Ovales of unequal bigness, others seemed to be set round with small globules, others had no globules in the Circumference, but several in the middle: these Globules I believe were at first swimming in the Watry liquor under the Ovales, tho now they cleave to them by Accedent.

Upon the Plate whereon I layd the Frog that I anatomized I found several Animals moving in a watry blood, they were about half as long and half as broad as the Oval Particles, and about 50 of them might lye in the space

of a fand, these I had never seen in the pure blood, nor could I perceive them in the water that came out upon ripping the skin from the flesh, or upon opening the belly, or squeezing the head of the Frog to make it lye quiet upon the Plate. At length in the moneth of June I met with some froggs whole excrement was full of an innumerable company of living Creatures, of different forts and fizes, the greatest fort were shaped like Fig. F and of these I judged that 40. might be in the space of a fand. The 2d. fort had the shape of Fig. G. these were but few in number. The 3d fort was like our River Eeles as Fig. H. and these were more in number then the first; But the whole excrement besides was so full of living things, that it feemed all to move, & I guest there was not less then 1000 of the third fort in the space of a sand. hence I concluded that the Animals found among the blood might come from my cutting a Gut.

By the way I observed something of the dammage that fregs may do to fish-ponds, for I took out of some of their

Stomacks 8. 10 or more young fishes.

I took notice of a small vein, of about the thickness of a hair of my head, that when the blood was out of it,

the Coat was like a frogs outward skin.

The same Coat of the vein was made of threds or filaments runing by the side of one another, just as if they had been wound close about a small round stich, so as to cover it all over. Now if there be Capillarys in the body a 1000 times less then this which I examined, how thin must the threds necessarily be of which the Coat is made? and how easily must these threds be separated and devided from one another, so as to let the blood when it is very forcibly moved in the Arterys, start out between them; and I was the more consirmed in this Opinion, upon spreading hard the Coat of the vein, for I then saw through it as through a hair sive, hence may a probable account be given of St. Anthonys sire, red swellings, or A a a

the Small pocks, and perhaps the blood may be more gently strained through these passages for the nourishing

of some parts of the body.

I examined one of the Muscles of the hinder leg of a frog, which confifted of filaments, and those again of a great number of lesser filaments, but because they had more rings in them then I had formerl feen in the mulcular threds of an Oxe, Fly, Gnat, Flea or Louse, I have here represented part of one in Fig. I. such numerous rings I have fince met with in the filaments of the Muscle of a Lamb, taken from the rim of the Belly, near the hinder leg. From the indentings of these filaments I cannot only latisfy my felf how the limbs come to stand bent, when the muscles are at rest, but also why we can walk a longer time then stand still; and why our Arms when we walk do not hang down at their full length, stretcht out by our fides; but more backwards and forwards; for if the Arms should still hang strait down, then would one Muscle be stretcht too much, and another bent or drawn up too close; both these things disagreeing with the Natural constitution of the Muscle, and for this reason it is, that when we fland a long time, we do not rest equally upon both legs, but first raise up one foot, then the other, touching the ground only with the fore part of the foot, while the Muscles of that leg rest themselves.

I have been puzzled why some of the wrincles in the filaments of Flesh and Fish muscles, were serpentine, as I represented in my letter of the 3d. of March (Fig. 1st. EEGH and IKLM.) but I consider that the filaments lose their roundness by being prest hard upon one another. It is also probable that they may be bent after that manner by the evaporating of their moysture, which makes up $\frac{2}{3}$ parts of their bulk: as Fig. Kabys. is a Filament which had been round, but is now alterd by the evaporating of its moysture, and bended in as at a, where-

by the rings that were formerly streight, appear serpentine, as between \$\beta\$ and \$\beta\$.

In a letter of mine to Mr. Oldenburg (which was not published) I affirmed, that Concoction was not performed by an Acidliquor dissolving our meat, but by the motion of the Stomach, and guts, which bruises, and breaks the meat to pieces. This motion is caused by the Diaphragme pressing upon the parts of the lower belly, as often as we take breath; in the same manner as a bladder almost full of water, is molded and rolled between the hands. There is also a natural marmth to be considered in the (tomach, and a natural folding or closing it self, about the Viduals which it holds, be it never so little; but especially there is a kneeding or contracting of themselves, remarqueable in the Bowels of beafts, even after they are taken out of the body. I am lately more confirmed in this opinion, by my observations on the Excrements of a Codfish. which I find to be made up of very short pieces of the Filaments of Fish, appearing by the Microscope like the shavings of ones Beard, for as in some Creatures the taking of breath, so in fishes the moving of the Gills, causes a compression and dilatation in the stomach, whereby the Aliment is catcht in its folds, nipt a funder, and divided into fuch small particles as are fit for the nourishment of their Now if the Contraction of the stomach be supposed to happen no oftner then a man breaths in an hour, there will be about 3000 times: which will be quickly enough to wast, and tear in pieces a little fish swallowed down by a great one, although the teeth of the Devourer, and the Acidjuice should contribute nothing to digestion.

Sometimes these threds are not to be found in the excrements, as perhaps when the Codfish has been long catcht; and without food, for then the threds are broken so short; that they are no bigger when they are voyded, then small Globules, which I judged to be for a blood Globule. When the Codfish has abundance of food, then the pieces of A a a 2 threds.

threds are droven the faster out of the *stomach*, and through the *Bowels*, and therefore are the less broken and shortned.

Such like Filaments or pieces of flesh I have observed in my one Excrements, which I conceive were made by the nipping of the folds of the stomack: for these Filaments are not strong, when there lye yut sew of them together; or when we make a Cord or Rope of them, which upon stretching bears unequally; though in another case a muscle made up of several of these filaments, and bearing equally in every part, may be very strong.

I have often maintaind among our Pyhlicians, that tho the heart and Pulse beat quicker then ordinary, yet the Circulation of the blood is not performed in leffer time; and the reasons which I gave were these. The blood in many Feavorilb persons is very thick, and therefore passes flowly, and with difficulty, thro the smaller Arterys, and requires a very strong beating in the heart to force its When the blood is thick and makes this resistance, the heart upon contracting it felf, cannot force it all out, but a great part remains behind in the Ventricles. remaining blood being over heated by the heart, makes that little blood which comes fresh out of the Veins, too hot likewise; and in the mean time the heart not being able to free it self of all the blood contained in its Cavities, casts out only the thinner part, which is quickly spent in the nourishment of the body, whereby the blood still becomes thicker, and circulates less fast. I can not admit that the time of the circuite of the blood, should be estimated by the number of Pulses in an hour, and the capacity of the Cavitys of the heart; for as the Lungs upon expiratiou are never totally without air, fo the heart in a well constituted body, is never upon the Sistale absolutely with out blood: I imagine also that when the heart is too full of blood (as I have before urged) its mufcles may be fo far strained, and kept beyond their usual bent, that they

[355]

they would not be relaxed, tho the blood were very thin, and fit for motion; just as we see the bladder by being keptlong too sull of mater, has the Muscles so reacht, that they can not be contracted. So also the Easterne People who would acquire to themselves the reputation of Saints, remain with their Limbs so long stretcht out in one posture, that they can not draw them back again.

An
